**Abstract** -- It is obvious to harness the intermittent renewable energy resources, energy storage applications, such as a lithium-ion battery, are very important.  $\alpha$ -type  $\text{MnO}_2$  is considered as an attractive cathode material for lithium-ion battery due to its relatively large ( $2 \times 2$ ) tunnel structure, remarkable discharge capacity, low cost, and environmental benignity. However, low intrinsic electronic conductivity of  $\alpha$ -type  $\text{MnO}_2$  limits its full utilization as a cathode for a lithium-ion battery. Therefore, studies to enhance the  $\alpha$ -type  $\text{MnO}_2$  properties are undoubted of great interest. While previous computational studies have been focused on pristine  $\alpha$ -type  $\text{MnO}_2$ , in the present report, we present the theoretical research on potassium-intercalated  $\alpha$ -type  $\text{MnO}_2$  using first principle Density Functional Theory calculations for the first time. Our results showed that potassium-intercalated  $\alpha$ -type  $\text{MnO}_2$  improved the electronic conductivity which beneficial for energy storage application. The structural transformation of potassium-intercalated  $\alpha$ -type  $\text{MnO}_2$  upon lithium insertion are also discussed. Our results may open the avenue for further utilization of potassium-intercalated  $\alpha$ -type  $\text{MnO}_2$  materials for not only the lithium-ion battery but also other type energy storage systems.

### INTRODUCTION

Owing to the high population growth, indeed the demand for energy becomes unavoidable. Fossil-based energy, as one of the primary energy resources, is declining because oil reserves are dwindling (Nayak et al., 2018). Moreover, depending on the fossil-based energy is detrimental to our environment. Therefore, alternative energy resources, known as renewable energy such as solar, wind, tidal and geothermal energies have been intensively studied.

Nevertheless, these renewable energies are intermittent, and consequently, these systems should also have the ability to store the generated energy (Supegina & Imam, 2014). In this situation, rechargeable batteries as energy storage will be very urgent. Lithium-ion batteries (LIBs) are becoming a primary choice to fulfill that demand because of their high energies and power densities (Drewett et al., 2017; Nayak et al., 2018).

Besides, various technology advancement products such as digital cameras, drones, smartphones, laptops and some cases of tiny computers (Raspberry Pi) require batteries to power them (Divya & Ostergaard,

2009; Adriansyah et al., 2014; Supegina & Iklimia, 2015).

Transition metal oxides (TMOs) are one of the most attractive active materials for LIBs, particularly manganese oxides. In comparison with other TMOs such as Co and Ni-based oxides, Mn-based oxides are commonly used as cathode materials due to their low cost, low toxicity, and remarkable electrochemical performance (Li et al., 2018). Manganese dioxides ( $\text{MnO}_2$ ) is amongst Mn-based oxides that have received great attention from the battery community. For example, Kim and co-workers reported the use of  $\text{MnO}_2$  nanoflakes prepared via a reduction technique in basic medium (Kim et al., 2018). The cathode showed discharge and charge capacities of 477 and 223 mAh  $\text{g}^{-1}$  could be obtained at a current rate of 20 mA  $\text{g}^{-1}$  in the initial cycle. Moreover, the cathode exhibited 93% capacity retention after 200 cycles.

$\text{MnO}_2$  is known to exist in various crystallographic forms, for instance,  $\alpha$ -,  $\beta$ -,  $\gamma$ -,  $\delta$ -,  $\lambda$ -, and  $\epsilon$ -type depending on how the fundamental unit of  $\text{MnO}_6$  octahedral are connected, for example *via* edge- and/or corner-shared (Julien & Mauger, 2017). The  $\alpha$ -

$\beta$ - and  $\gamma$ -type exhibit 1-dimensional tunnels in their structures with  $(2 \times 2)$ ,  $(1 \times 1)$ , and a combination of  $(1 \times 1)$  and  $(2 \times 1)$  tunnels, respectively. The  $\delta$ -type has a 2-dimensional layered structure, while the  $\lambda$ -type shows a 3-dimensional spinel structure. Because of its  $(2 \times 2)$  tunnel structure,  $\alpha$ -type has obtained much interest in LIB applications experimentally as well as computationally. The large  $(2 \times 2)$  tunnels facilitate the facile hosting/release of the charge carrier ions.

Density Functional Theory (DFT) is considered as an essential tool to study electrode materials properties for a battery application. DFT can be used to predict the structure, energetics, and electrochemical properties of electrode materials. As for  $\alpha$ -type  $\text{MnO}_2$  as LIB cathode, several reports studied its structure and Li-intercalation behavior. However, to the best of our knowledge, those reports have been focused on the primary and  $\text{Li}_2\text{O}$ -intercalated  $\alpha$ -type  $\text{MnO}_2$ , while it is widely known that initial  $\alpha$ -type  $\text{MnO}_2$  possesses low intrinsic electronic conductivity and leads to poor electrochemical properties (Ling & Mizuno, 2012; Tompsett & Islam, 2013). Therefore, in this contribution, we aim to fill the gap by performing DFT calculation to study the K-intercalated  $\alpha$ -type  $\text{MnO}_2$  structure and its Li-insertion properties for the first time. Our present study may provide an additional understanding to use K-intercalated  $\alpha$ -type  $\text{MnO}_2$  for a battery application. The potassium was selected in this study due to the potassium-containing precursors such as  $\text{KMnO}_4$  is commonly used to synthesize  $\alpha$ -type  $\text{MnO}_2$ . Literature also records that particular alkali-ion also plays a significant role in forming  $\alpha$ -type  $\text{MnO}_2$  with a tetragonal system (Kitchaev et al., 2018).

## METHOD

In this work, we performed density functional theory (DFT) calculations as implemented in the Quantum-Espresso package using projector augmented wave (PAW) pseudopotential and Perdew-Burke-Ernzerhof (PBE) exchange-correlation functional (Giannozzi et al., 2009).

A plane-wave basis set with a cutoff of 25 Ry (340 eV) was used for all calculations. The atoms in the  $\alpha$ -type  $\text{MnO}_2$  structure (space group  $I4/m$ ) were relaxed using Broyden-Fletcher-Goldfarb-Shanno (BFGS) scheme with energy and force convergences criteria of  $1 \times 10^{-4}$  Ry and  $1 \times 10^{-3}$  Ry/Bohr, respectively, wherein all the axes and angles were permitted to move freely.

The Brillouin zone was sampled using a k-point mesh of  $3 \times 3 \times 3$  and  $1 \times 1 \times 2$  supercells was used. All crystallographic figures were drawn using VESTA software (Momma, Izumi, 2011).

## RESULTS AND DISCUSSION

LIB commonly consists of anode, cathode, and electrolyte. The anode is generally made from carbon (graphite) for full cell configuration or Li metal anode for half-cell system while the cathode is typically formed from a transition metal compound such as oxide or phosphate-based compound. In principle, LIBs work in mostly the same way.

Individually, when the battery is discharging, the lithium ions move across the electrolyte to the cathode, generating the energy that can power up the electronic devices, and reversely, when the battery is charging up, the cathode releases its Li-ions, which move to the anode through the electrolyte. The LIB mechanism is illustrated in Fig. 1. Amongst transition metal oxide compounds,  $\text{MnO}_2$ , particularly  $\alpha$ -type  $\text{MnO}_2$  has obtained a significant interest.

Figure 1. Illustration of LIB components and its corresponding mechanism.

$\alpha$ -type  $\text{MnO}_2$  has a relatively large  $(2 \times 2)$  tunnels along the  $c$ -axis within the structure.  $\alpha$ -type  $\text{MnO}_2$  also exhibits tetragonal symmetry which belongs to  $I4/m$  space group (No. 87).  $\alpha$ -type  $\text{MnO}_2$  built of edge-shared  $\text{MnO}_6$  octahedral units, and its structure is shown in Fig. 2, while the formation of K-intercalated  $\alpha$ -type  $\text{MnO}_2$  is depicted in Fig. 3. In the present study, the

intercalated K is located in the center of the ( $2 \times 2$ ) tunnels of  $\alpha$ -type  $\text{MnO}_2$  structure ( $2a$  sites). Literature recorded that metal-intercalated  $\alpha$ -type  $\text{MnO}_2$  enhanced the electrical conductivity, for example, Co- or V-intercalated  $\alpha$ -type  $\text{MnO}_2$ . Due to the relatively high cost and toxicity of cobalt and vanadium, thus potassium is used. Potassium is considered low cost, abundance and environmentally benign.

Figure 2. Illustration of  $\alpha$ -type  $\text{MnO}_2$  crystallographic structure. Red color is oxygen while blue is  $\text{MnO}_6$  octahedral unit.

Figure 3. Illustration of K-intercalated  $\alpha$ -type  $\text{MnO}_2$  crystallographic structure. A big purple sphere is K.

The calculated unit cell parameters of the relaxed pristine  $\alpha$ -type  $\text{MnO}_2$  structure were  $a = b = 9.45$  and  $c = 2.79$  Å, and the values are in agreement with the experimental results previously reported (Johnson, et al., 1997). After K-intercalation, the unit cell parameters were calculated to be  $a = b = 9.53$  and  $c = 2.79$  Å. Also, the unit cell volumes of the relaxed pristine

and K-intercalated  $\alpha$ -type  $\text{MnO}_2$  were 250.32 and 253.91 Å<sup>3</sup>, respectively; thus, the K-intercalation into  $\alpha$ -type  $\text{MnO}_2$  only expands the unit cell slightly, i.e., approximately 1.4%, without collapsing the structure. The expansion also advantages for further Li-ion insertion/extraction into/from the structure.

To study the improved electrical conductivity of K-intercalated  $\alpha$ -type  $\text{MnO}_2$ , a density of state (DOS) calculations were performed. The total DOS for pristine and K-intercalated  $\alpha$ -type  $\text{MnO}_2$  are shown in Fig. 4. It can be seen that the initial  $\alpha$ -type  $\text{MnO}_2$  showed semiconducting behavior with a distinct bandgap, while the K-intercalated  $\alpha$ -type  $\text{MnO}_2$  showed occupied spin-down states inside the pristine  $\alpha$ -type  $\text{MnO}_2$  bandgap, indicating the enhanced conductivity of  $\alpha$ -type  $\text{MnO}_2$  after K-ion intercalation.

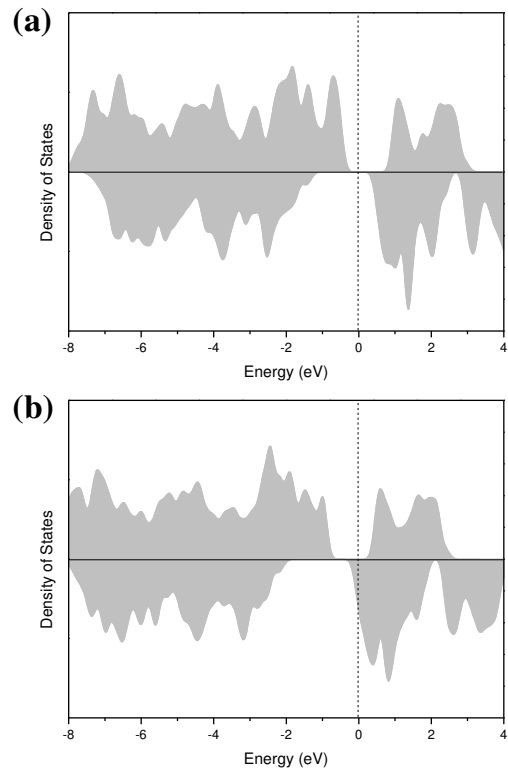

Figure 4. Electron density of states of (a) primary  $\alpha$ -type  $\text{MnO}_2$  and (b) K-intercalated  $\alpha$ -type  $\text{MnO}_2$  calculated using DFT.

For use as cathode materials for LIBs, studies of the insertion of Li-ion into  $\alpha$ -type  $\text{MnO}_2$  suggested that the tunnels might facilitate the insertion. In the present case, since K-ions is located at  $2a$  sites, we consider at least two possible sites for Li-ions to reside, namely  $2b$  and  $8h$  sites, depicted in Fig. 5a.  $2b$  sites are positioned at the center of the ( $2 \times 2$ ) tunnels

adjacent to  $2a$  sites, whereas  $8h$  sites are situated close to  $2a$  and  $2b$  sites with a small deviation, toward the pseudocubic walls (Fig. 5b).

Figure 5. Possible insertion sites in  $\alpha$ -type  $\text{MnO}_2$  structure. (a)  $8h$  and (b)  $2b$  sites.

Cause of considering the above-mentioned available sites in the  $(2 \times 2)$  tunnels, the Li-ions were further the added and structural relaxations were also performed. In the beginning, we calculated the dilute limit of Li-insertion. Specifically, only one Li-ion was put in a  $1 \times 1 \times 2$  supercell of  $\alpha$ -type  $\text{MnO}_2$  structure (16 Mn and 31 O atoms). In the dilute limit, the compound composition is expressed as  $\alpha$ -type  $\text{Li}_1\text{K}_2\text{Mn}_{16}\text{O}_{32}$  or  $\alpha$ -type  $\text{Li}_{0.0625}\text{K}_{0.125}\text{MnO}_2$ . The insertion energy was calculated as a function of concentration using Equ. (1).

$$E_l = E_{\text{Li}_1\text{K}_2\text{Mn}_{16}\text{O}_{32}} - E_{\text{K}_2\text{Mn}_{16}\text{O}_{32}} - E_{\text{Li}} \quad (1)$$

where  $E_{\text{Li}_1\text{K}_2\text{Mn}_{16}\text{O}_{32}}$  is the energy of  $\text{Li}_1\text{K}_2\text{Mn}_{16}\text{O}_{32}$ ,  $E_{\text{K}_2\text{Mn}_{16}\text{O}_{32}}$  is the energy of  $\text{K}_2\text{Mn}_{16}\text{O}_{32}$  and  $E_{\text{Li}}$  is the energy of Li.

Our calculation suggested that the site preference for Li-ion in the dilute limit is  $8h$  site due to an  $8h$  site having lower insertion energy compared to that of a  $2b$  site within 40 meV. Our calculation is in agreement with the previous report (Tompsett & Islam, 2013). We note that the structural model used in the Tompsett and Islam's calculation was pristine  $\alpha$ -type  $\text{MnO}_2$ , whereas, in our report, we employed K-intercalated  $\alpha$ -type  $\text{MnO}_2$ . However, a similar tendency was also found in our present results. We note also that the Li-ion insertion in the dilute limit increases the unit volume ca. 0.87%. It is also worth mentioning here that the insertion of Li-ion in the dilute limit results in a slight change of the joint angle between  $\text{MnO}_6$  octahedral units from  $82.12$  to  $83.15^\circ$ .

We then proceeded our calculations for Li-ion insertion into  $\alpha$ -type  $\text{MnO}_2$  structure beyond the dilute limit and the calculated lattice parameters and unit cell volumes are presented in Table 1. For the concentration of  $\text{Li}_{0.125}\text{K}_{0.125}\text{MnO}_2$ ,  $\text{Li}_{0.25}\text{K}_{0.125}\text{MnO}_2$  and  $\text{Li}_{0.5}\text{K}_{0.125}\text{MnO}_2$ , the calculated unit cell volumes were 258.25, 262.57 and  $278.21 \text{ \AA}^3$ , respectively. Interestingly, the calculated  $a/b$  ratio for the  $\text{Li}_{0.5}\text{K}_{0.125}\text{MnO}_2$  is 1. The  $a/b$  ratio is commonly used to indicate Jahn-Teller distortion phenomena when it shows a value larger than 1 within the concentration  $\text{Li}_{0.5}\text{MnO}_2$ . Here, the K-intercalation is shown to effectively stabilize the structure. This will be beneficial for long term cycling of the electrode.

Table 1. Calculated lattice parameters and unit cell volumes for lithium-inserted  $\text{K}_{0.125}\text{MnO}_2$

Composition	a (Å)	b (Å)	c (Å)	V (Å <sup>3</sup> )
$\text{Li}_{0.125}\text{K}_{0.125}\text{MnO}_2$	9.51	9.72	2.79	258.25
$\text{Li}_{0.25}\text{K}_{0.125}\text{MnO}_2$	9.69	9.69	2.79	262.57
$\text{Li}_{0.5}\text{K}_{0.125}\text{MnO}_2$	9.87	9.87	2.85	278.21
$\text{Li}_{1.0}\text{K}_{0.125}\text{MnO}_2$	10.12	10.12	2.82	289.43

Fig. 6 illustrates the structure of  $\alpha$ -type  $\text{Li}_{0.5}\text{K}_{0.125}\text{MnO}_2$ . The structure remains tetragonal symmetry after the insertion of 0.5 moles of lithium. It was previously reported the insertion of other cation such as Mg (0.5 moles) cause severe deformation of  $\alpha$ -type  $\text{MnO}_2$  structure. Ling et al. highlighted that the  $\alpha$ -type  $\text{MnO}_2$  structure was barely maintained (Ling & Mizuno, 2012).

Figure 6. Relaxed  $\alpha$ -type  $\text{Li}_{0.5}\text{K}_{0.125}\text{MnO}_2$  structure.

Furthermore, from Fig. 7 it is obvious that the unit cell of  $\alpha$ -type  $\text{MnO}_2$  structure expanded largely causing the stretch of the octahedral  $\text{MnO}_6$ . The final  $a$  and  $c$  lattice parameters were 10.12 and 2.82 Å, while the unit cell volume 289.43 Å<sup>3</sup>. However, the unit cell volume change was only about 13.8%, which is lower than that of pristine  $\alpha$ -type  $\text{MnO}_2$  after 1-mole Li-ion intercalation (Tompsett & Islam, 2013). Therefore, the strategy of using K-intercalation in  $\alpha$ -type  $\text{MnO}_2$  structure may be useful for further development of monovalent as well as multivalent battery systems.

Figure 7. Relaxed  $\alpha$ -type  $\text{K}_{0.125}\text{MnO}_2$  structure after 1-mole Li-ion insertion showing the stretch of  $\text{MnO}_6$  octahedral unit.

## CONCLUSION

In conclusion, we have performed first-principles calculations to assess the insertion

behavior of Li-ion in K-intercalated  $\alpha$ -type  $\text{MnO}_2$  structure for Li-ion battery-based energy storage. Our estimates suggest the preferred Li-insertion site in K-intercalated  $\alpha$ -type  $\text{MnO}_2$  structure is an  $8h$  site. We also show that K-intercalation into  $\alpha$ -type  $\text{MnO}_2$  strategy may increase the electronic conductivity and further prevent large unit cell volume expansion upon Li-ion insertion, by only 13.8% after 1 mole of Li-ion insertion, which is lower than that of pristine  $\alpha$ -type  $\text{MnO}_2$ . Finally, this study provides theoretical information for further use and development  $\alpha$ -type  $\text{MnO}_2$  structure in energy storage system towards its practical application and commercialization.
