**ABSTRACT**

Ixodid ticks were collected from seven species of endemic murid rodents and from vegetation in Sulawesi Utara, Indonesia. Adult ticks belonging to the species, *Amblyomma babirussae*, *A. cyprium* and *Dermacentor (Indocentor) steini* were taken from the vegetation. Immature ticks assignable to the genera, *Haemaphysalis*, *Amblyomma* and *Ixodes* infested the murids with *Parauromys dominator* and *Maxomys musschenbroekii* being the two most heavily tick-infested host species. The data are compared to other tick records from Sulawesi.

**INTRODUCTION**

Ectoparasites were collected from murid rodents live-trapped in Sulawesi Utara (North Sulawesi), Indonesia, on August 1985. We report here on the ticks (Ixodidae) collected during this project. Eighty five murids belonging to seven species, all endemic to Sulawesi, were examined for ticks. The comparatively small size of these host animals made infestation by adult ticks (which are identifiable to the species level) unlikely, so adult ticks were taken from vegetation when possible to supplement the collections. Collection data for the 58 ticks recovered from the murids and from vegetation are given below, listed by collection locality. Specimens are currently in the Rocky Mountain Laboratory collections (now at the Smithsonian Institution, Washington, Washington B.C., U.S.A.) and accession numbers are also given. Mammal specimens are either with collections of the South Australian Museum or the Museum Zoologicum Bogoriense, Indonesia; their original collection numbers are presented here.

1. Gunung Moajat (0°45'N 124°25'E). Elevation, 1800 m. From - vegetation. *Amblyomma cyprium* Neumann (1Q)

- Ex. *Parauromys dominator* (CHSW No. 114)

*Haemaphysalis* sp. (IN)
  - Ex. *R. hoffmanni* (CHSW No. 138)  
*Amblyomma* sp. (4L, 4N - 2 of these nymphs belong to one species and 2 to a second species)
- 4. Gunung Mogogonipa (0°27'N 123°57'E). Elevation, 1008 m.
  - On vegetation

*Amblyomma babirussae* (19) *Dermacentor* (*I.*)  
*steini* Schulze (19)

5. By 'Lake' (0°44'N 124°27'E). Elevation, 1080-1200 m. - Ex. P.  
*dominator* (CHSW No. 13) *Haemaphysalis* sp. (IN)

\*L = Larvae, N = Nymphs.

The three species of adult ticks that were collected are fairly well known. *Amblyomma babirussae* (Figure 1) represents part of the endemic tick fauna of

Figure 1. *Amblyomma babirussae* (adult female).

Sulawesi; adults are parasitic principally on larger artiodactyls and on endemic and feral pigs (Suidae) (Anastos 1950, Keirans and Robbins 1987) while immatures are parasitic on these same hosts and also on murids (Keirans and Robbins 1987, Van Peena *et al.* 1974). Adults of *A. babirussae* are also known to attach to humans (Keirans and Robbins 1987). *Amblyomma cyprium* (Figure 2) has a wide distribution in the Indo-Pacific region (Anastos 1950; Kohls 1957; Wilson 1969; Marshall 1976; Kemp and Wilson 1979) with adults again parasitic largely on wild and feral pigs, but also on humans and cattle, and immatures on a variety of smaller hosts,

Figure 2. *Amblyomma cyprium* (adult female).

particularly murids (Kohls 1957; Kemp and Wilson 1979). *Dermacentor (I.) steini* (Figure 3) has recently been redescribed by Wassef and Hoogstraal (1986) who document a wide distribution for this species in Indo-Malaysia (including the Philippines and with establishment on Papua New Guinea); however, they give no records for Sulawesi so the present collections extend the documented range for this tick.

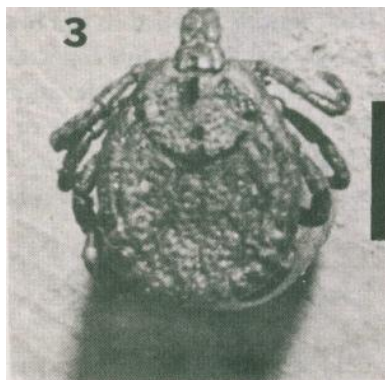

Figure 3. *Dermacentor (Indocentor) steini* (adult female).

*Dermacentor (I.) steini* adults again appear to be parasitic mainly on wild and feral pigs (Wassef and Hoogstraal 1986).

Unfortunately, adults of an undescribed species of tick probably assignable to the genus, *Amblyomma*, collected by Durden (1986) as a single nymphal specimen (Accession No. HH112,315 in the Hoogstraal tick collection is now housed at the Smithsonian Institution, Washington D.C., USA) from a murid, *M. musschenbroekii*, in Sulawesi Utara, were not collected. This immature specimen is so atypical that Hoogstraal (personal communication) could not be certain of its taxonomic status and hopefully, future ectoparasite collections from Sulawesi will produce adults of this fascinating tick.

Analysis of the prevalence of tick infestation from the murid species examined shows that no ticks were taken from the 13 *Bunomys fratrorum* or from the 11 congeneric *B. chrysocomus* rats processed. The other five murid species showed various levels of infestation. *Rattus hoffmanni* (n = 10) showed a collective tick (three genera represented) prevalence of 40% and a mean intensity of 3.0 ticks per infested animal. The other murid species had the following comparable infestation figures:

- R. xanthurus* (n = 7)(1 tick genus), 14.3%, 2.0;
- P. dominator* (N = 16)(2 tick genera), 31.3%, 3.4;
- M. musschenbroekii* (n = 17)(3 tick genera), 23.5%, 4.8;
- M. hellwaldii* (n = 11)(1 tick genus), 9.1%, 4.0.

The main difference between these data and those of Durden (1986) is that, in this study, no *Dermacentor (Indocentor)* sp. ticks were collected from murids. In the earlier survey, *B. fratrorum* and especially *M. musschenbroekii* were quite heavily infested by ticks of this subgenus; this difference could reflect a seasonal influence. Another difference, possibly attributable to phenology, is the presence of *Ixodes* sp. immatures from murids trapped in the lowland forests (200-300 m elevation) of Dumoga-Bone National Park in this collection; Durden (1986) did not record this genus from murids from comparable elevations in this forest. The earlier collection (Durden 1986) was made from January to March, 1985, during the latter part of the monsoon season (although heavy rains were not as concentrated into this season as is typical for much of Southeast Asia).

#### ACKNOWLEDGMENTS

Deep gratitude is extended to Dr. I.E. Keirans who identified the ticks described here and to Dr. G.G. Musser for confirming host identities. Appreciation is also extended to R.G. Robbins for cataloguing ticks, to Dr. N.A. Wilson for sup-

plying separates and to the late Dr. H. Hoogstraal for his personal communications and earlier tick identifications. This research was undertaken as part of Project Wallace organized by the Royal Entomological Society of London and the Indonesian Institute of Sciences (Results of Project Wallace No. 30).
